Key Messages

Key messages for this weekly report are presented below.

Rainfall and its forecast

- During Mar 28-Apr 3, rainfall was observed from Chiang Khan to Thakhek stations and from Kratie to Chua Doc along the Mekong River, while no rainfall at other stations.
- There will be warm temperatures for the next 7 days over the Mekong region from 04 to 13 April 2023.

Water level and its forecast

- The MRC's observed water level (WL) at Jinghong showed a stable WL at 535.27 m during 28 Mar-3 Apr 2023. The outflow showed at 851.00 m³/s between 28 Mar and 3 Apr 2023.
- With the stable outflow at Jinghong upstream, water level of monitoring station at Chiang Saen in Thailand went down about 0.15 m during the reporting period and stayed 0.86 m below its LTA, considered low level. WLs at the monitoring stations at Chiang Khan in Thailand significantly decreased about 0.85 m, staying 0.70 m below its LTA value, while at Vientiane in Lao PDR it significantly decreased about 0.67 m and stayed about 0.28 m below its LTA value. The current WL at Nong Khai in Thailand was about 0.79 m lower than its LTA value, while at Paksane in Lao PDR it was about 0.34 m lower than its LTA level, which considered low water level. WLs from Thailand's Nakhon Phanom to Pakse increased between 0.13 m and 0.29 m. WLs at these stations are slightly staying higher than their LTA value, considered normal. Water levels from the stretches of the river from Stung Treng to Kratie in Cambodia, moreover, were slightly increasing and still staying higher than their LTA value due to contributed inflows and some rainfall from the upstream part (at Pakse and 3S area in Viet Nam). WL at Kompong Cham is about 0.37 m lower than its LTA value.
- The water volume of the Tonle Sap Lake was slightly lower than its LTA during the same period from 28 Mar to 3 Apr 2023, considered normal.
- The current water levels for most of the stations are below their LTA value, except at Luang Prabang, Nakhon Phanom, Thakhek, Mukdahan, Savannakhet, Khong Chiam, Pakse, Stung Treng, Kratie and Neak Luong. WLs at the 2 tidal stations at Tan Chau and Chau Doc fluctuated between their minimum and LTA values, during this monitoring period.
- Over the next seven days, the water levels across most monitoring stations are expected to go down and remain lower than their long-term average value in most stations.

Drought condition and its forecast

- During Mar 27-Apr 2, the LMB was much better than the previous week of Mar 20-26. However, moderately dry condition remained in most areas of the middle and lower parts covering from Chaiyaphum of Thailand to Savannakhet of Lao PDR in the east

and down to Kampot of Cambodia and Dak Lak of Viet Nam. Those specific drought hotspots are considered normal as they are caused by dry soil moisture phenomenon during dry season.

- For the coming three months, **March** is generally wet in the north and south while middle part is likely to be normal. **April** is forecasted to receive average rainfall all over the region. But **May** is likely to be severely dry over the 3S area and moderately dry in the south-east covering eastern part of Cambodia and Viet Nam.

1 Introduction

This Weekly Dry Season Situation Report presents a preliminary analysis of the weekly hydrological situation in the Lower Mekong River Basin (LMB) for **28 March-3 April 2023**. The trend and outlook for water levels are also presented.

This analysis is based on the daily hydro-meteorological data provided by the Mekong River Commission (MRC) Member Countries – Cambodia, Lao PDR, Thailand, and Viet Nam – and on satellite data. Water level indicated in this report refers to an above zero gauge of each station.

The report covers the following topics that are updated weekly:

- General weather patterns, including rainfall patterns over the LMB
- Water levels in the LMB, including in the Tonle Sap
- Flash flood and drought situation in the LMB
- Weather, water level and flash flood forecast, and
- Possible implications.

Mekong River water levels are updated daily and can be accessed from:
http://ffw.mrcmekong.org/bulletin_wet.php.

Drought monitoring and forecasting information is available at:
<http://droughtforecast.mrcmekong.org>

Flash flood information is accessible at: <http://ffw.mrcmekong.org/ffg.php>

2 General Weather Patterns

The weather outlook bulletins for three months (April, May and June) and the weather maps issued by the Thai Meteorological Department (TMD) were used to verify weather conditions in the LMB.

Since the end of March 2022, the warm weather has appeared because the influentially high-pressure air mass areas prevail over the LMB, with gradually decreasing water levels in both mainstream and tributaries. The data from the TMD predict that low pressure of air-mass will continue warm weather condition in the upper part of Thailand, Lao PDR and Viet Nam. As a result, the temperature in the upper part of Thailand will rise sharply as commonly warm and hot weather, specifically at the upper portion of the northern and north-eastern parts together with very hot weather in mountainous areas (within the Mekong region).

[Figure 1](#) presents the weather map on 30 March 2023, indicating that no low-pressure cell was active in the South-Sea of Viet Nam, having no impact in the LMB. Generally, the Mekong region was influenced by easterly and southerly winds with high-pressure cell southern LMB and the divergence area (high-pressure cell) in the Bay of Bengal. Under this weather condition, there was light to moderate rainfall occurred in the northern and central parts of LMB, 3S area, and northern and Central Viet Nam.

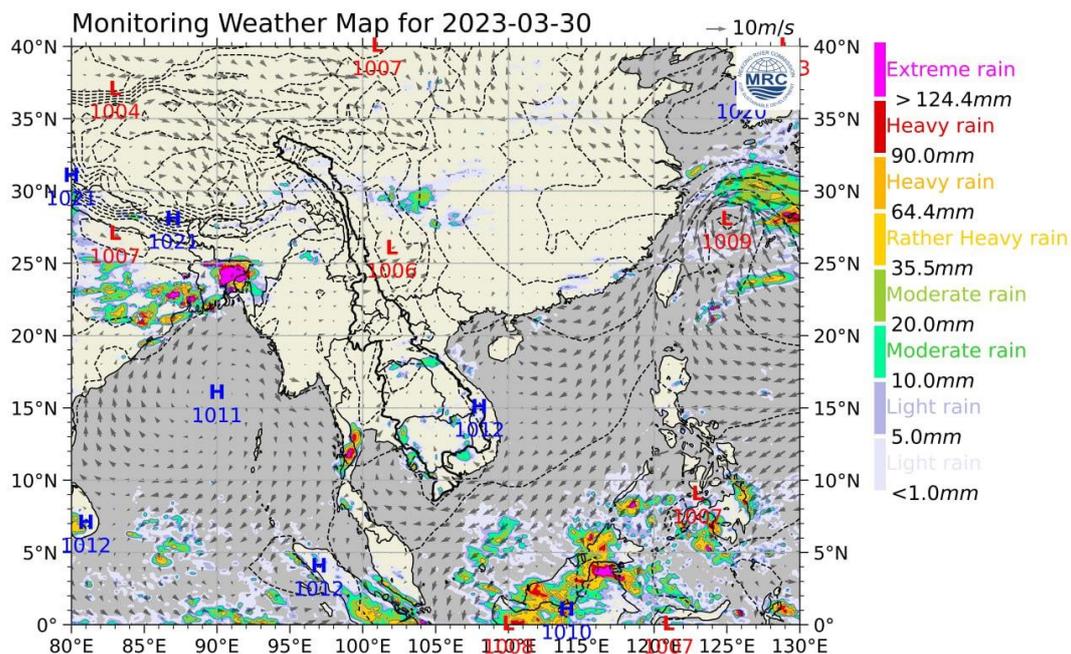

Figure 1: Summary of weather conditions over the LMB.

According to the ASEAN Specialised Meteorological Centre (ASMC), a highest probability of drier condition is predicted over the lower part of the Mekong region covering Lao PDR and Thailand from 3 to 16 April 2023. **Figure 2** shows the outlook of weather condition from 3 to 16 April 2023 in Southeast Asia based on results from the NCEP model (National Centres for Environmental Prediction).

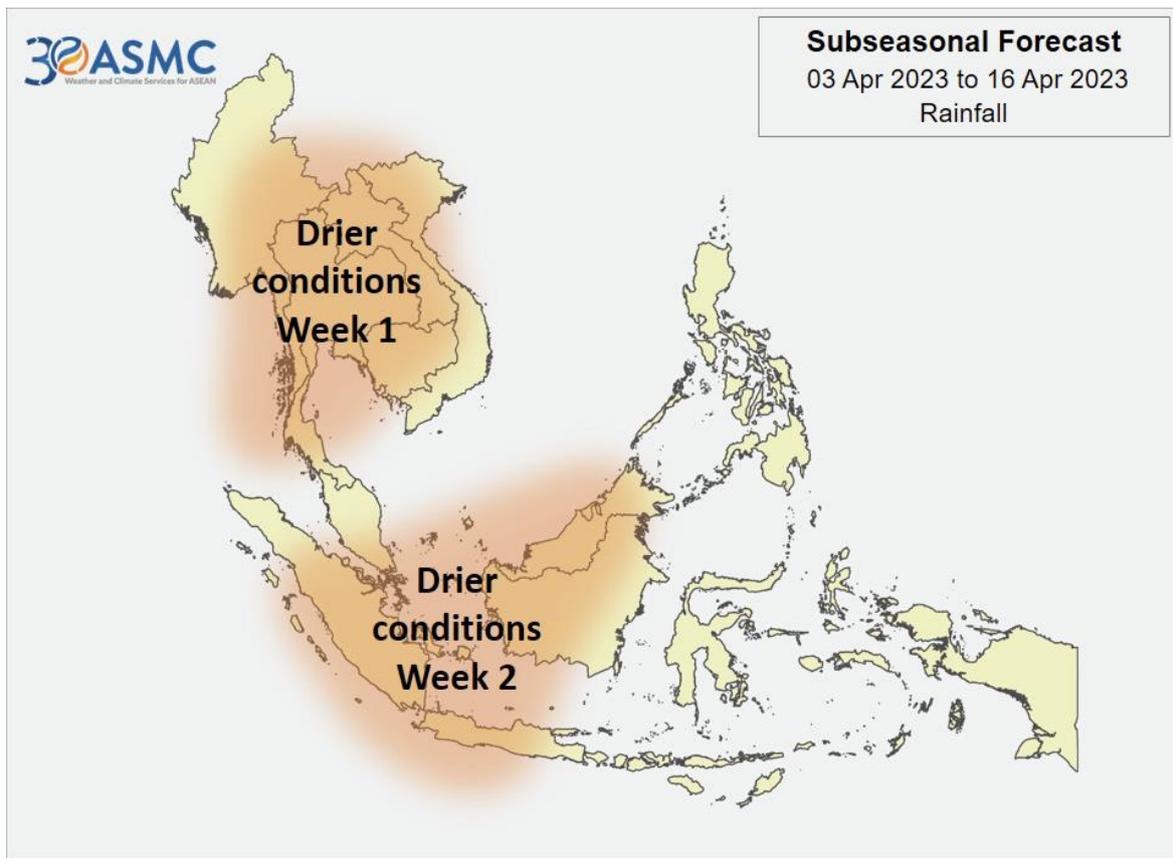

Figure 2: Outlook of wet and dry conditions over the Asian countries by ASMC.

Tropical depressions (TD), tropical storms (TS) and typhoons (TY)

There was a tracking storm covering the LMB during 28 March-3 April 2023, showing no low-pressure line over the LMB. No movement of storm was detected over Viet Nam, as displayed in [Figure 3](#).

Active system as of 3 Mar 2023, 13:42 GMT

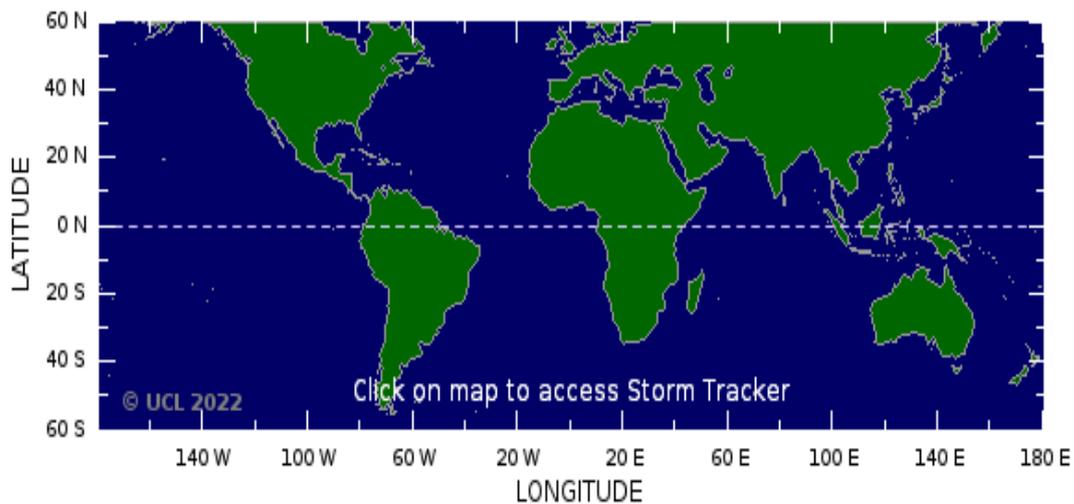

Figure 3: No tropical storm risk observed on 3 April 2023.

Rainfall patterns over the LMB

This week from 28 March to 3 April 2023, rainfall was observed from Chiang Khan in Thailand to Thakhek in Lao PDR and also from Kratie in Cambodia to Chau Doc in Viet Nam along the Mekong River of the Lower Mekong Basin (LMB). The highest rainfall was about 29.60 mm at Paksane in Lao PDR. The total rainfall of this week report in the Mekong region compared with last week and its long-term-average (LTA) is showed in [Figure 4](#).

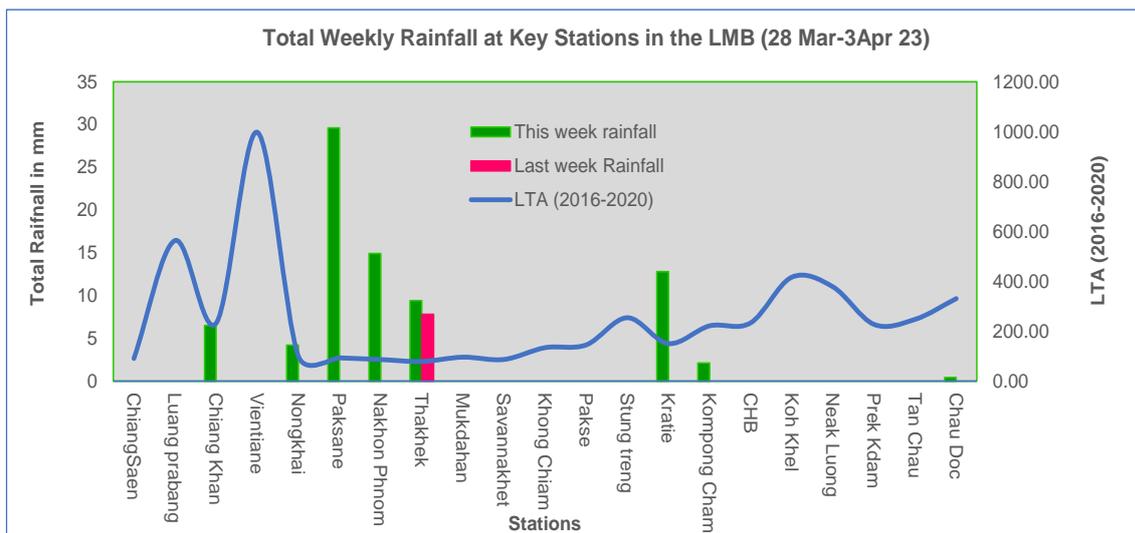

Figure 4: Weekly total rainfall at key stations in the LMB.

To verify area rainfall distribution, [Figure 5](#) shows a map of the weekly accumulated rainfall based on the observed data provided by the MRC Member Countries – Cambodia, Lao PDR, Thailand, and Viet Nam – from 28 Mar to 3 Apr 2023.

Absence of rain this week is an indication of the end of the rainy season in the LMB.

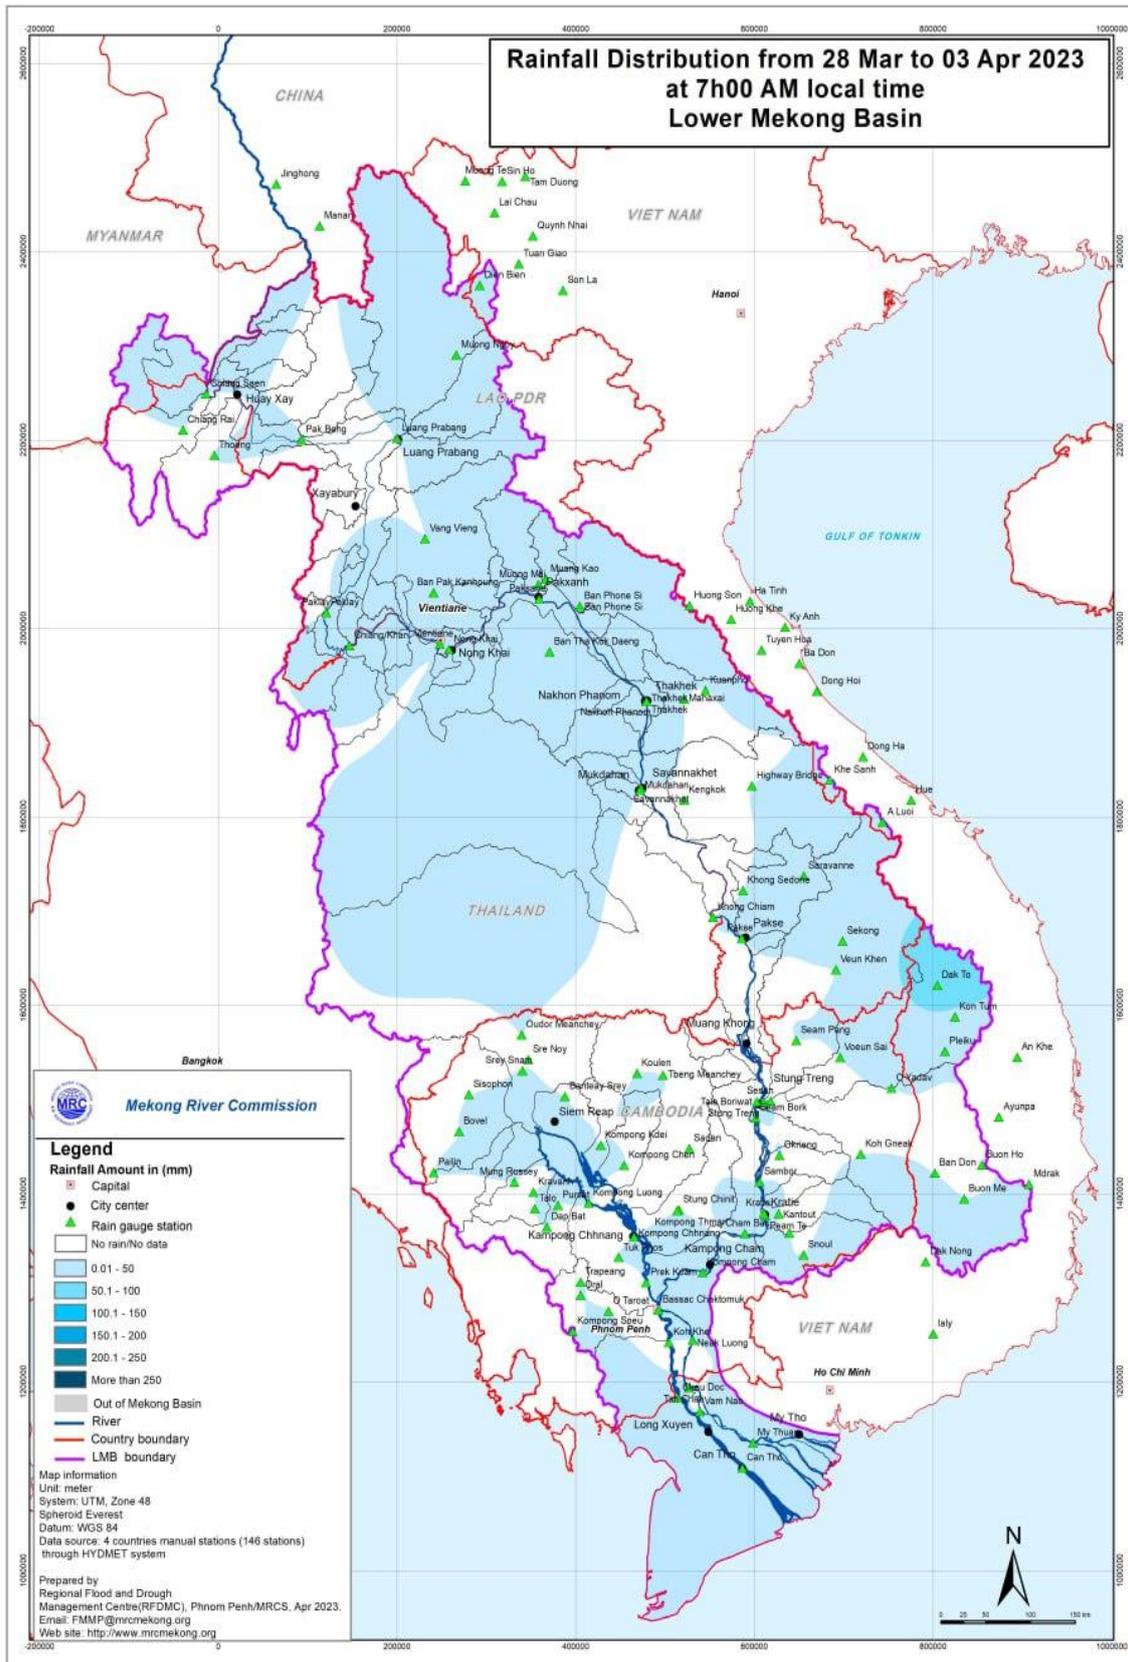

Figure 5: Weekly rainfall distribution over the LMB.

3 Water Levels in the Lower Mekong River

The hydrological regimes of the Mekong mainstream are illustrated by recorded water levels and flows at key mainstream stations: at Chiang Saen to capture mainstream flows entering from the Upper Mekong Basin (UMB); at Vientiane to present flows generated by climate conditions in the upper part of the LMB; at Pakse to investigate flows influenced by inflows from the larger Mekong tributaries; at Kratie in Cambodia to capture overall flows of the Mekong Basin; and at Viet Nam’s Tan Chau and Chau Doc to monitor flows to the Delta.

The key stations along the LMB and their respective model application for River Flood Forecasting during the wet season from June to October and River Monitoring during the dry season from November to May are presented in [Figure 6](#). The hydrograph for each key station is available from the MRC’s River Flood Forecasting: <http://ffw.mrcmekong.org/overview.php>. The weekly water levels and rainfall at each key station are summarised in **Annex A**.

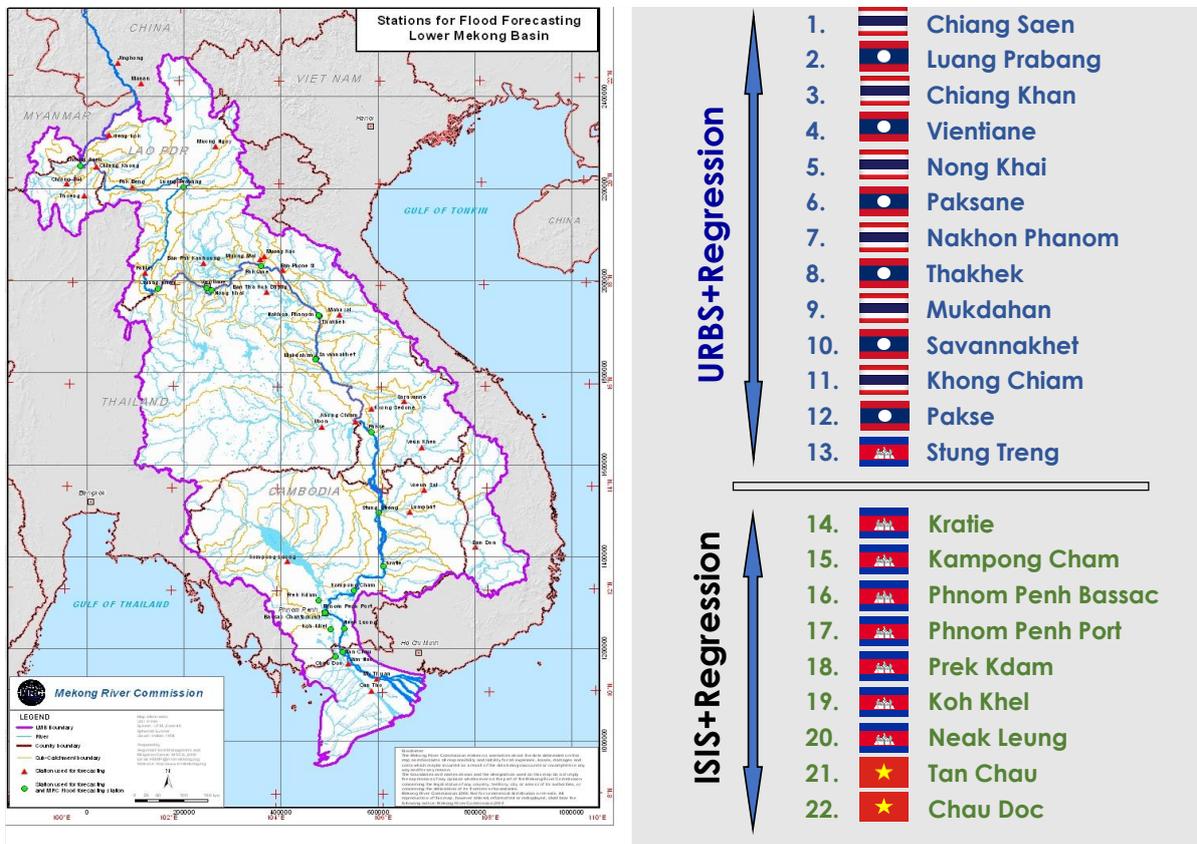

Figure 6: Key stations and model application for River Monitoring and Flood Forecasting.

The MRC’s observed water level (WL) at Jinghong showed almost stable values in between 535.27 m to 535.28 m from 28 Mar to 3 Apr 2023 (recorded on 7:00 am). The outflow varied from 851.00 m³/s to 845.00 m³/s between 28 Mar and 3 Apr 2023.

[Figure 7](#) below presents water level that decreased at the Jinghong hydrological station¹, indicating the trend of fluctuating water level up to 3 April 2023.

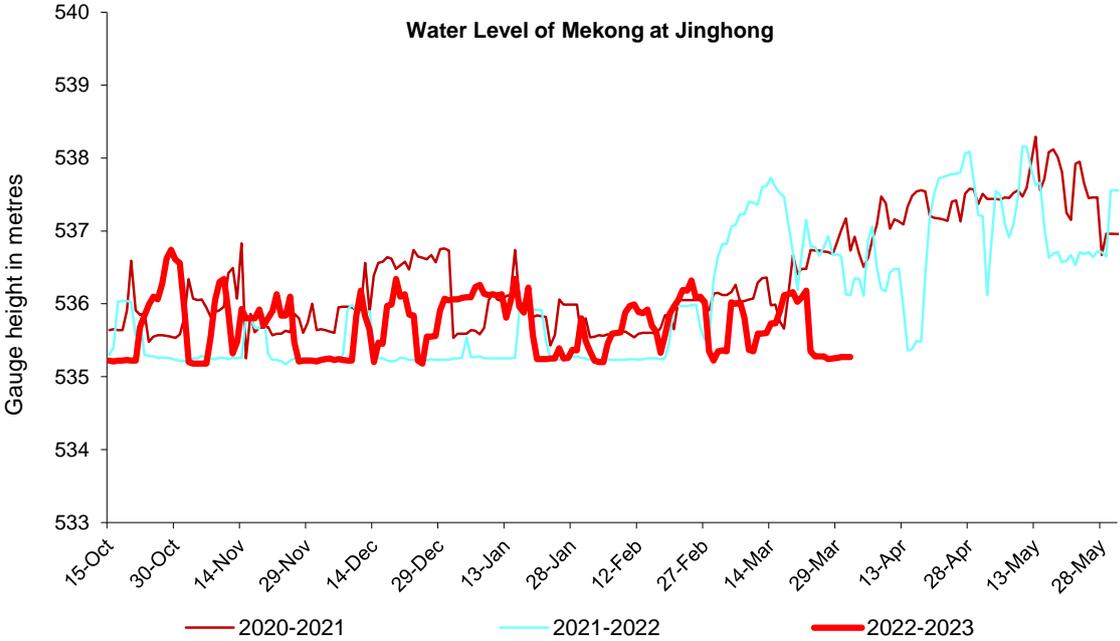

Figure 7. Water level at the Jinghong hydrological station during 28 March-3 April 2023.

Amit the stable outflow from Jinghong upstream, water level of monitoring station at Chiang Saen in Thailand decreased 0.15 m from 28 Mar to 3 Apr 2023 and stayed about 0.86 m lower than its long-term average (LTA), which considered low level. WLs at the monitoring station at Chiang Khan in Thailand sharply decreased about 0.85 m and stayed 0.70 m lower than its LTA, while at Vientiane in Lao PDR it decreased about 0.67 m and stayed about 0.28 m below its LTA value, considered low water levels. The current WLs from Nong Khai in Thailand, furthermore, decreased 0.45 m and stayed 0.79 m lower than its LTA, while at Paksane in Lao PDR it decreased about 0.20 m and stayed 0.35 m lower than its LTA value. WLs at these stations were considered low. Water levels from Nakhon Phanom in Thailand to Pakse increased between 0.13 m and 0.29 m. WLs at these stations are staying slightly above their LTA value. Water levels from the stretches of the river from Stung Treng to Kratie in Cambodia, moreover, were increasing by 0.14 m and 0.08 m respectively. The water levels at and at Kompong Cham decreased about 0.11 m due to inflow and contributed rainfall from the upstream part. WLs at Stung Treng and Kratie were staying about 0.34 m and 0.42 m higher than their LTA value, respectively. WL at Kompong Cham was about 0.37 m lower than its LTA value.

Based on hydrological phenomenon, the contribution of inflow water from the upstream of Lancang-Mekong in China to the Mekong mainstream is about 16% in total during the wet season from June to October and about 25% in total during the dry season from November to

¹ Near-real time data of hydro-meteorological monitoring at the Jinghong hydrological station is available at <https://portal.mrcmekong.org/monitoring/river-monitoring-telemetry>.

May. The whole inflow of water into the LMB is influenced by rainfall at the Mekong mainstream and its tributaries during the wet season.

Chiang Saen and Luang Prabang

Water level during 28 Mar-3 Apr 2023 at Thailand’s Chiang Saen decreased from 1.61 m to 1.47 m, staying about 0.86 m lower than its Long-Term-Average (LTA), which is considered low level. When compared to last week, this week’s water level is relatively lower.

Water level at the Luang Prabang station in Lao PDR decreased from 8.78 m to 8.46 m, during the reporting period. Compared to last week, the figure shows it is down about 0.32 m. The water level at this station was 2.66 m higher than its LTA value and staying about 0.64 m below its historical maximum value. The water levels at Chiang Saen and Luang Prabang are shown in [Figure 8](#) below.

Being situated between the upstream (Nam Beng, Nam Ou, Nam Suong, and Nam Khan) and downstream (Xayaburi) hydropower dams, the Luang Prabang station has a unique characteristic as it is influenced by the operations of all its surrounding dams. **Thus, the water level at this station can possibly change very rapidly during the early dry season.**

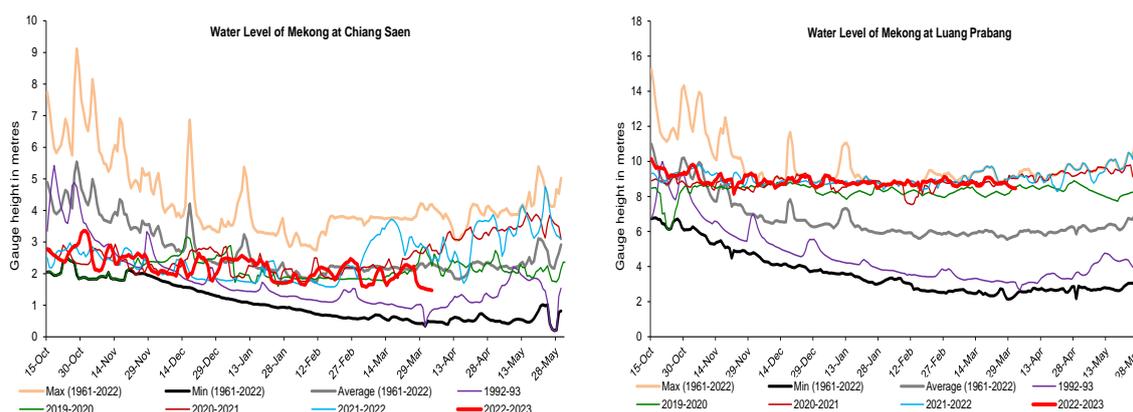

Figure 8. Water levels at Chiang Saen in Thailand and Luang Prabang in Lao PDR.

Chiang Khan, Vientiane-Nong Khai and Paksane

The water level at Chiang Khan in Thailand (downstream of the Xayaburi dam) sharply decreased about 0.85 m, during the reporting week. It showed 0.70 m above its LTA. Also, water level downstream at Vientiane in Lao PDR also decreased from 1.90 m to 1.23 m and stayed about 0.28 m lower than its LTA during 28 Mar-3 Apr 2023. At Nong Khai station in Thailand, the water level decreased about 0.45 m during the reporting period. It showed 0.79 m lower than its LTA value, which still considered low water level. At Paksane in Lao PDR, water level decreased about 0.20 m staying about 0.35 m lower than its LTA value. The recently decreased water levels were obviously due to low inflow from upstream and water operation from upstream in the sub-catchment area. The water levels at Vientiane and Paksane are shown in [Figure 9](#) below.

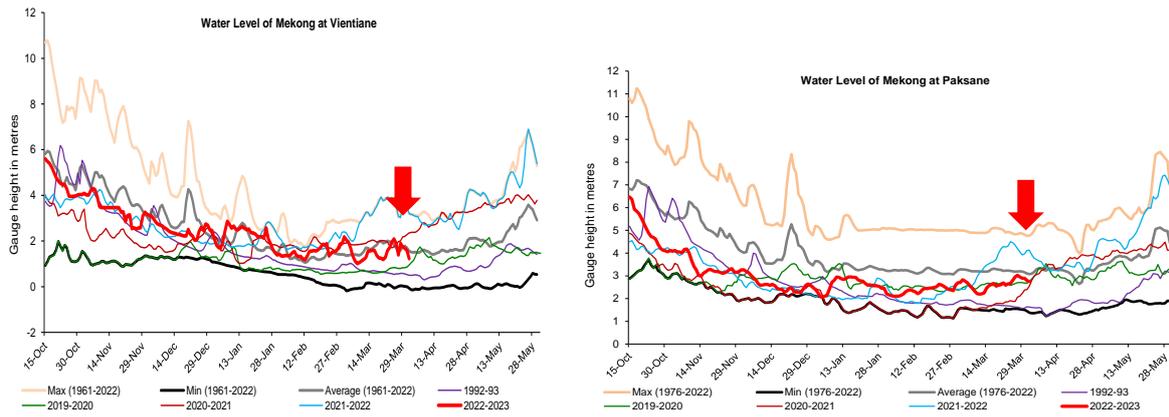

Figure 9. Water levels Vientiane and Paksane in Thailand and Lao PDR.

Nakhon Phanom to Pakse

Moreover, water levels from Nakhon Phanom in Thailand to Pakse in Lao PDR increased between 0.13 and 0.29 m, which staying slightly higher to their LTA level. The water levels of those stations were slightly higher than their LTA value, considered normal. [Figure 10](#) shows the water levels at Nakhon Phanom and Pakse stations.

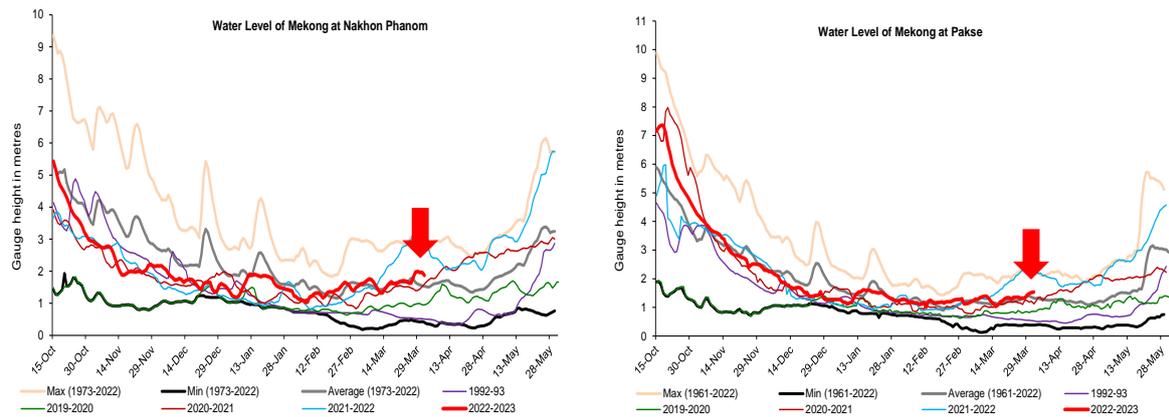

Figure 10: Water levels at Nakhon Phanom and Savannakhet of Thailand and Lao PDR.

Stung Treng to Kompong Cham/Phnom Penh to Koh Khel/Neak Luong

Although there was no rainfall from the upstream part of the Mekong River and the 3S river (Sekong, Se San, and Sre Pok), the water levels from Stung Treng to Kratie in Cambodia were still increasing during 28 Mar-3 Apr 2023. The water level Stung Treng increased about 0.14 m, while at Kratie it increased about 0.08 m. Water levels at Stung Treng and Kratie are staying about 0.34 m and 0.42 m higher than their LTA value, respectively. Water levels at these two stations were considered high during the dry season (as showed in [Figure 11](#)).

This week, the water levels at Kompong Cham were down about 0.11 m and stayed 0.37 m below their LTA value, which considered normal.

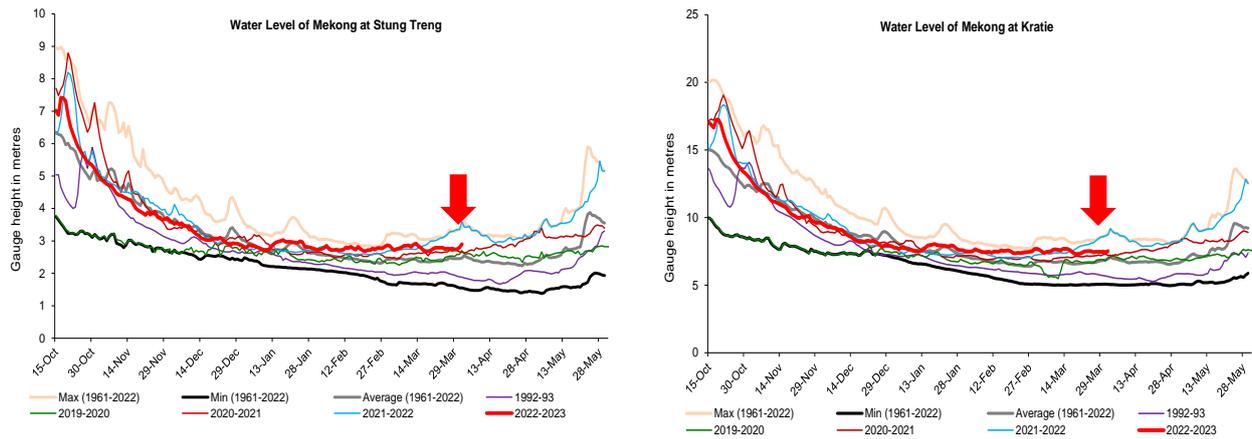

Figure 11: Water levels at Stung Treng and Kratie on the Mekong River.

At Chaktomuk on the Bassac River, the water level was down by about 0.08 m and stayed 0.28 m lower than its LTA value; while at Koh Khel, water level decreased about 0.26 m, staying 0.37 m lower than its LTA value. It was observed that the WLS at Koh Khel and Neak Luong were affected by tidal from downstream stations of Tan Chau and Chau Doc in Viet Nam, during the dry season period. However, water level at Prek Kdam on the Tonle Sap Lake was stable at 1.04 m and stayed 0.08 m lower than its LTA value. The water level at the Tonle Sap Lake (observed at Kompong Luong) was similar to Prek Kdam station's water level. The recently decreased water level was due to absence of rainfall and less inflow contributed from upstream of the Tonle Sap Lake area during the reporting period. The water level at the Tonle Sap Lake (observed at Kompong Luong) followed the same trend of Prek Kdam station's water level. **Water levels at these stations were mostly staying lower than their LTA level, which still considered low water level.**

Tidal stations at Tan Chau and Chau Doc

Like last week, the water levels from 28 Mar to 3 Apr 2023 at Viet Nam's Tan Chau and Chau Doc were fluctuating between their LTA and minimum values due to daily tidal effects from the sea. The fluctuated levels were between -0.31 m and 0.62 m. In Tan Chau and Chau Doc, the fluctuation of water levels at these stations were lower than their LTA level, which **considered critical.**

The Tonle Sap Flow

At the end of the wet season, when water levels along the Mekong River subside, the outflows of the Tonle Sap Lake return to the Mekong River and then to the Delta. This phenomenon normally takes place between September and October. Based on flow observation at Prek Kdam, the outflow of the Tonle Sap Lake took place since 29 October 2022.

[Figure 12](#) shows the seasonal changes of the inflow/reverse flow and the outflow of the TSL at Prek Kdam in comparison with the flows of 2019-2021 and 2022, and their LTA level (1997-2022). Up to March 27 of this reporting period, **it was observed that the main outflow to Tonle Sap Lake decreased due to less rainfall and inflows from upstream.** This decreased outflow of Tonle Sap Lake was most likely caused by less inflows and rainfall from the catchment area. Up to this date, the outflow from the Tonle Sap Lake condition in 2022 is

higher than 2020, 2021 and 2022 outflow conditions. It is noted that the outflow in early 2023 is still slightly lower than its LTA. For next week, less rainfall is forecasted for the Tonle Sap area; thus, the outflow into the Tonle Sap Lake is likely continuing to decrease from the current level.

[Figure 13](#) shows seasonal changes in monthly flow volumes up to 3 April 2023 for the Lake compared with the volumes in 2020, 2021, 2022 and their LTA, and the fluctuation levels (1997–2021). It shows that up to 3 April 2023, **the water volume of the Tonle Sap Lake was staying slightly lower than its LTA (about 88 %) and higher than 2020, 2021, 2022 during the same period**. The figure is displayed in [Table 1](#), which indicates that the Tonle Sap Lake has been affected by water levels from the Mekong River, the tributaries, and rainfall in the surrounding sub-catchments and ***considered normal***.

This demonstrates the influence of the relationships between the reverse flows, water levels of the Mekong River, inflows from tributaries, and the flow direction in the complex hydraulic environment of the Tonle Sap Lake during the wet and dry seasons. The data show that about half of the annual inflow volume into the Tonle Sap Lake has originated from the Mekong mainstream. Thus, flow alterations in the mainstream could have direct impact on the Tonle Sap Lake water levels and on its hydrology.

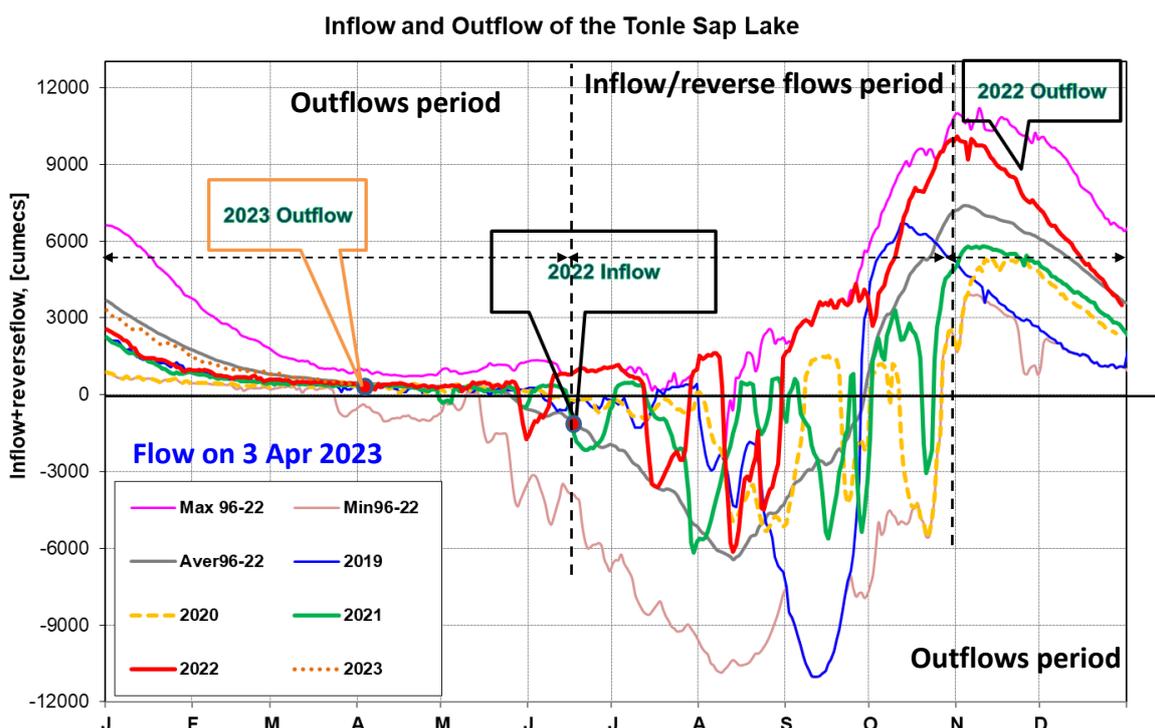

Figure 12: Seasonal change of inflows and outflows of Tonle Sap Lake.

4 Flash Flood in the Lower Mekong Basin

During the monitoring weekly from Mar 28 to Apr 3, the LMB area was affected by two main weather patterns. On 28 and 29 Mar 2023, the northeastern area was affected by the weakening high-pressure system; and from 30 Mar to 3 Apr 2023, the heat low-pressure system covered almost the entire of LMB. These conditions caused hot temperature, light rain, and thunderstorms in some areas of the LMB.

According to the MRC-Flash Flood Guidance System (MRC-FFGS) and analysis, flash flood events were not detected during the reporting period over the LMB.

5 Drought Monitoring in the Lower Mekong Basin

Weekly drought monitoring from 27 March to 2 April 2023

Drought monitoring data for 2023 are available from Monday to Sunday every week; thus, the reporting period is normally delayed by one day compared to Flood and Flash Flood reports. We adopt the Index of Soil Water Fraction (ISWF) data obtained from FFGS to represent soil moisture of agricultural indicator for both dry and wet seasons.

- **Weekly Standardised Precipitation Index (SPI1)**

Meteorological drought condition of the LMB from Mar 27 to Apr 2, as shown in [Figure 11](#), was moderately and severely dry in the middle and lower parts covering mainly Thailand and Cambodia. The drought areas covered Chaiyaphum, Surin, Buriram, Maha Sarakham, Roi Et, Yasothon, Amnat Charoen, Sakon Nakhon, Nakhon Phanom, Mukdahan, Ubon Ratchathani, Khammuane, Attapeu, Champassack, Savannakhet, Bateay Meanchey, Battambang, Preah Vihea, Kampong Thom, Modulkiri, Kampot, Takeo, Dak Lak, and Gia Lai.

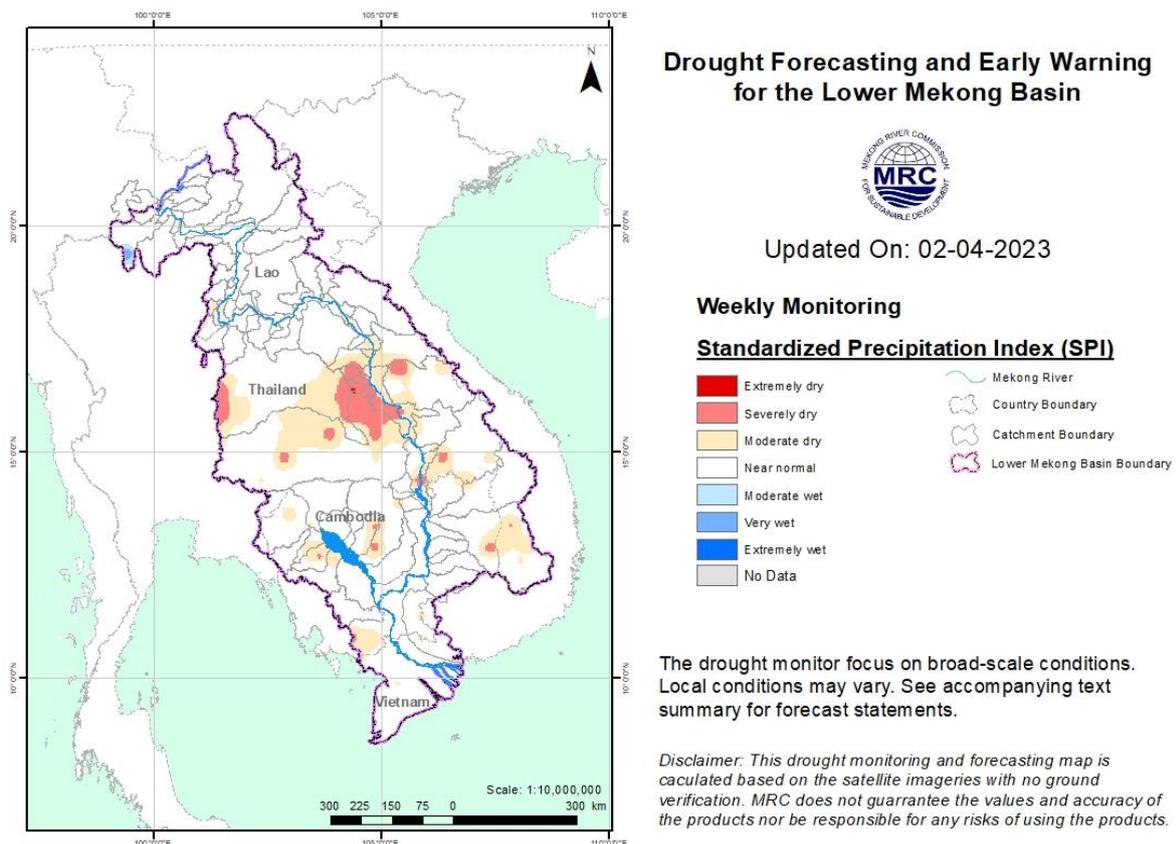

Figure 14: Weekly standardised precipitation index from Mar 27 to Apr 2.

- **Weekly Index of Soil Water Fraction (ISWF)**

Soil moisture condition from Mar 27 to Apr 2, as displayed in [Figure 12](#), were severely dry in some areas in the middle and southern parts of the LMB. The situation was much better than the previous week (Mar 20-26)/ However, this condition is normal during dry season and is very much similar to the condition last week.

Note: The index of soil water fraction presents the current soil water fraction conditions compared with normal month; therefore, it normally shows extremely dry during dry season which is completely different from SPI that is standardized to its specific month of the years. However, this does not mean that the areas are threatened by agricultural drought as generally during transition period of wet and dry seasons and dry season only the irrigated areas are used for agricultural plantation.

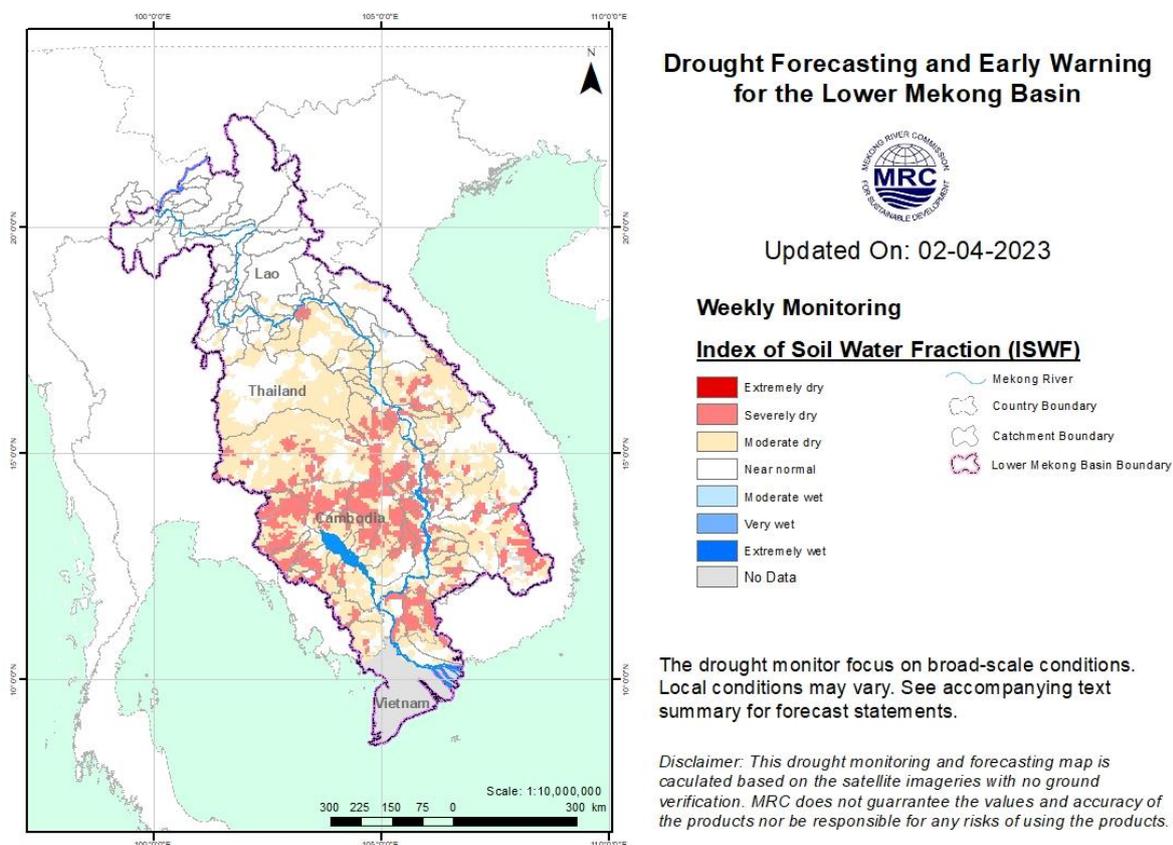

Figure 15: Weekly Index of Soil Water Fraction from Mar 27 to Apr 2.

- **Weekly Combined Drought Index (CDI)**

The combined drought indicator, as displayed in [Figure 13](#), reveals that during Mar 27-Apr 2 the LMB was much better than the previous week of Mar 20-26. However, moderately dry condition remained in most areas of the middle and lower parts covering from Chaiyaphum of Thailand to Savannakhet of Lao PDR in the east and down to Kampot of Cambodia and Dak Lak of Viet Nam. Those specific drought hotspots are considered normal as they are caused by dry soil moisture phenomenon during dry season.

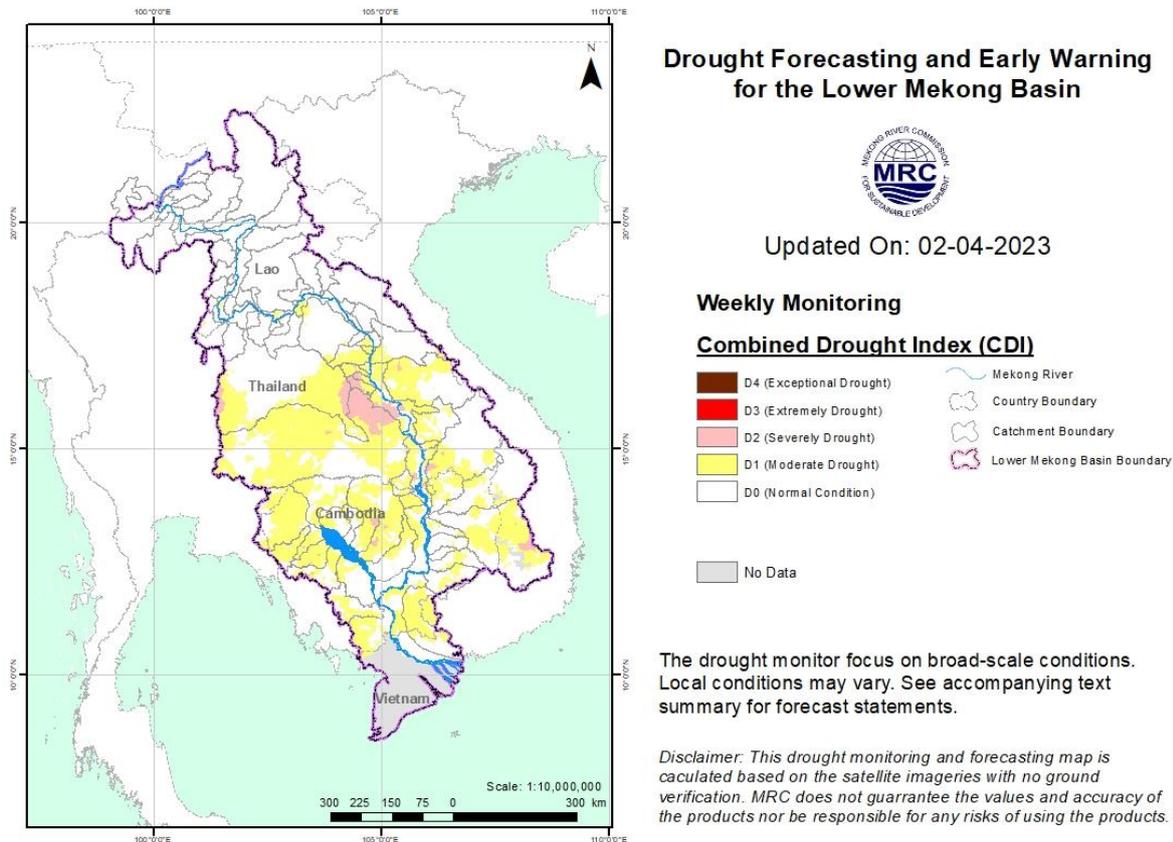

Figure 16: Weekly Combined Drought Index during Mar 27-Apr 2.

More information on Drought Forecasting and Early Warning (DFEW) as well as the explanation is available here: <http://droughtforecast.mrcmekong.org/templates/view/our-product>. DFEW provides not only weekly monitoring and forecasting information but also a three-month forecast of drought indicators with seasonal outlook which are updated every month based on international weather forecast models. Details on drought forecast are described in section [6.4](#) of this report.

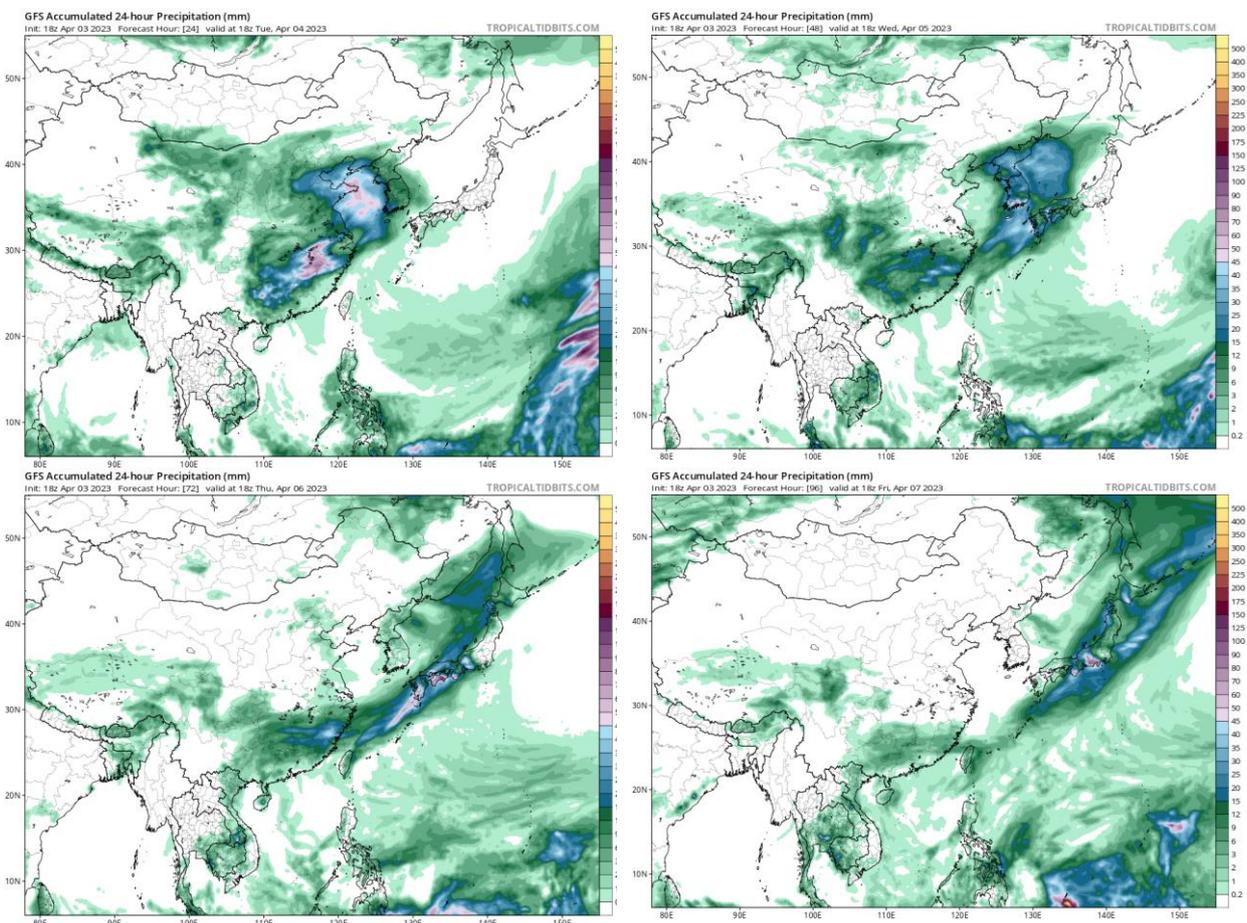

6 Weather and Water Level Forecast and Flash Flood Information

6.1 Weather and rainfall forecast

Based on the result of the Global Forecast System (GFS) model, the LMB area was affected by two main weather patterns during Mar 28-Apr 3. In the period from 04 to 06 Mar 2023, the LMB was affected by the heat low-pressure system, and from 07 Mar to 09 Apr 2023, the strengthening high-pressure system from the North prevailed over this area; then from 10 Apr 2023 onwards it is likely to weaken.

Under the weather forecast patterns for Apr 4-10, light rain and thunderstorms are likely taking place in some areas of the LMB. The maximum rainfall is about 5-20mm/24h.

[Figure 17](#) shows accumulated rainfall forecast (24hrs) of the GFS model during 04-10 April 2023.

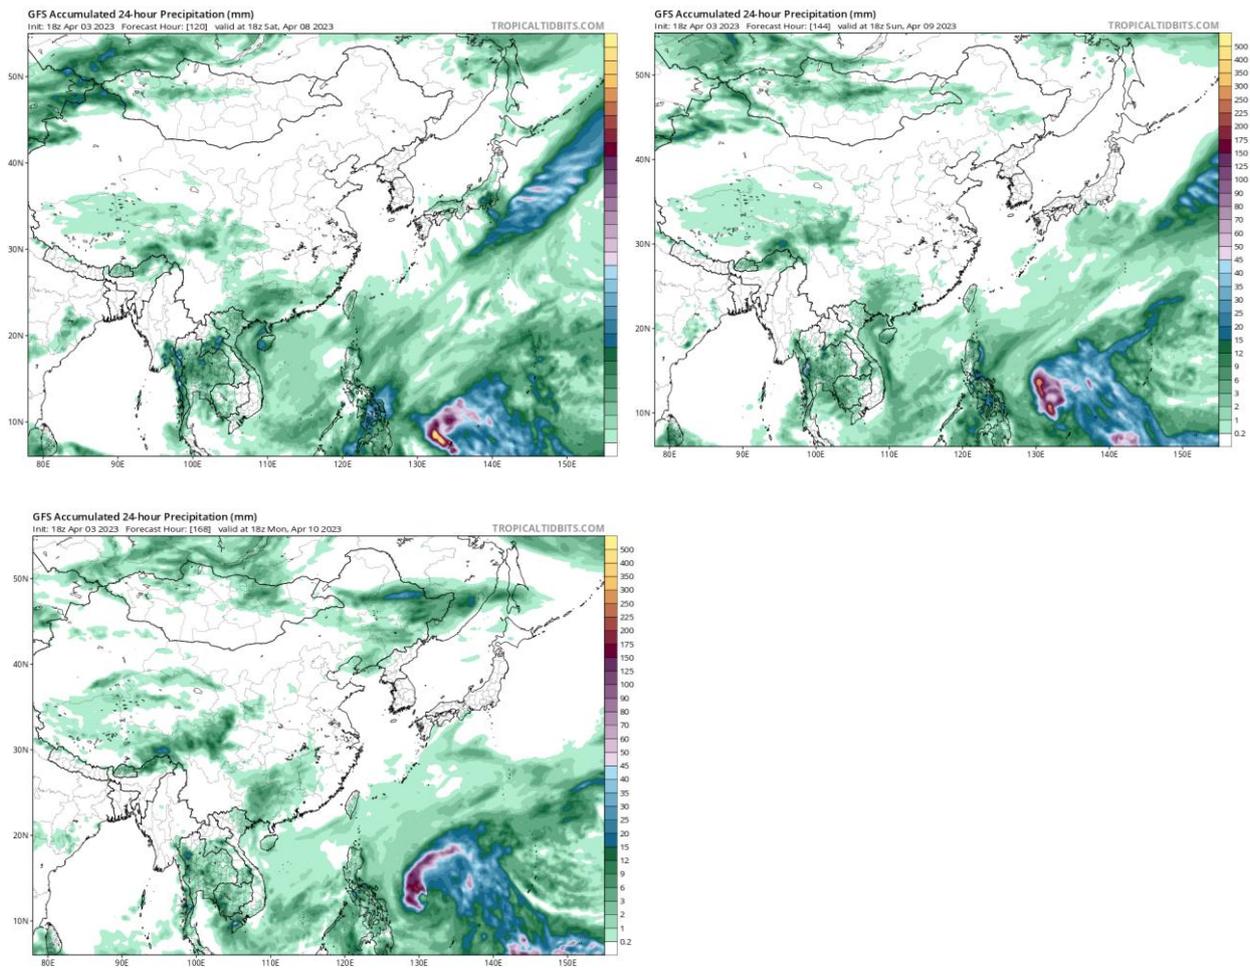

Figure 17: Accumulated rainfall forecast (24 hrs) of model GFS.

6.2 Water level forecast

Chiang Saen and Luang Prabang

Based on April 3's weekly river monitoring bulletin, the weekly forecast water level at Chiang Saen in Thailand is expected to increase from 1.47 m to 2.20 m in the next seven days. The trend of water levels at these stations will continue staying below its LTA.

For Luang Prabang in Lao PDR, the water level is likely increasing about 0.40 m during the same period. The current water level is about 2.66 m higher than its LTA and staying about 0.64 m lower than its historical maximum value.

Chiang Khan, Vientiane-Nong Khai and Paksane

Water level at Chiang Khan station in Thailand is forecasted to be up about 0.08 m for the next seven days. At Vientiane in Lao PDR and Nong Khai in Thailand WLS will be down between 0.05 m and 0.15 m in the next seven days. At Paksane in Lao PDR, water level will decrease about 0.05 m due to some effect of inflows from the upper catchments. No rainfalls are forecasted in the area due to no low pressure dominated in the upper sub-catchments. The water levels here will remain lower than their LTA.

Nakhon Phanom to Pakse

Water levels from Nakhon Phanom in Thailand to Pakse in Lao PDR will decrease between 0.04 m and 0.25 m. Water levels at these stations will stay close with their LTA level. Next week no precipitation is forecasted in the area.

Stung Treng to Kompong Cham/Phnom Penh to Koh Khel/Neak Luong

From Stung Treng on the Mekong River in Cambodia, the water level will likely go down about 0.10 m, while at Kratie it will be down about 0.05 m over the next seven days. For Kompong Cham, the WL will be up about 0.07 m and stay lower than its LTA. No rainfall is forecasted for the area between Stung Treng and Kompong Cham during next week.

The water levels of the Tonle Sap Lake at Prek Kdam and Phnom Penh Port as well as at Phnom Penh's Chaktomuk on the Bassac River will fluctuate between 0.03 m and 0.10 m over the next seven days.

Water levels at more than half of the stations will continue to stay lower than their LTA value, particularly in the lower part of the region from the Bassac in Phnom Penh to Koh Khel as well as from Tonle Sap in Prek Kdam to Phnom Penh Port, including the Tonle Sap Lake. No rainfall is forecasted for the low-lying area of Cambodia next week.

Tidal stations at Tan Chau and Chau Doc

For Viet Nam's Tan Chau on the Mekong River and Chau Doc on the Bassac River, water levels will be moving up between their LTA and minimum values following daily tidal effects from the sea.

[Table 3](#) shows the weekly River Monitoring Bulletin issued on April 3. Results of the started weekly river monitoring bulletin are also available at http://ffw.mrcmekong.org/bulletin_wet.php. Tables for weekly updated water levels and rainfall at the Key Stations are presented in **Annex A**.

6.3 Flash Flood Information

Flash flood events are not likely to happen in the LMB next week. However, local heavy rain in a short period of time might still be possible with unexpected short flash floods. During the dry season if extreme weather occurs, the information on flash flood guidance for the next one, three, and six hours is updated at <http://ffw.mrcmekong.org/ffg.php>.

Further detailed information on Flash Flood Information Warning, as well as on its explanation, is available for download [here](#).

6.4 Drought forecast

There are several climate-prediction models with different scenarios in the upcoming months. The MRC’s DFEWS adopts an ensemble model called the North America Multi-Model Ensemble (NMME), which averages all scenarios, and downscales the forecasts to the regional level. The Viable Infiltration Capability (VIC) is then used to generate soil moisture and runoff for the whole basin.

[Figure 18](#) below shows the NMME-based SPI forecasts for Mar, April, and May 2023 in over the LMB area.

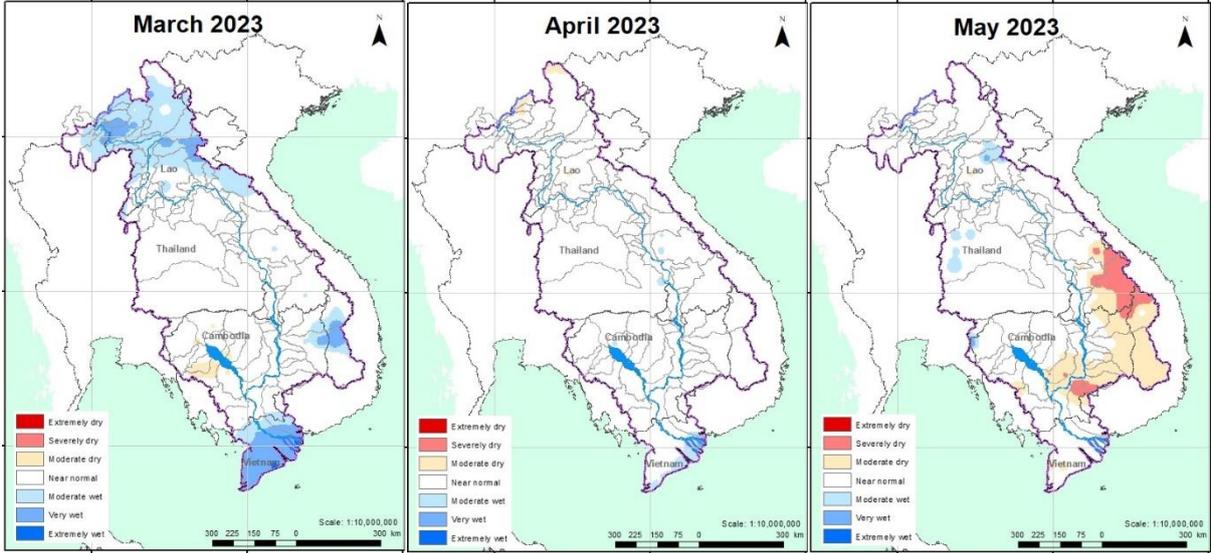

Figure 18. Monthly forecast of SPI for Mar, Apr, and May 2023.

Figure 18 above shows that in **March** is generally wet in the north and south while middle part is likely to be normal. **April** is forecasted to receive average rainfall all over the region. But **May** is likely to be severely dry over the 3S area and moderately dry in the south-east covering eastern part of Cambodia and Viet Nam.

7 Summary and Possible Implications

7.1 Rainfall and its forecast

This week, rainfall was observed from Chiang Khan to Thakhek stations along the Mekong River while other stations down to the lower part at Kratie and Chau Doc in Viet Nam no rainfall was detected. Compared with last week's amount, the rainfall this week was considered low in the Mekong region.

Based on the forecasted rainfall from satellite using GFS data, no rainfall is forecasted in the areas from the lower part of Cambodia to the 3S area and Mekong Delta in Viet Nam from 04 to 13 April 2023. This indicates that the warm and hot weather in dry season has spread all over the LMB.

7.2 Water level and its forecast

The MRC's observed water level (WL) at Jinghong showed a stable level at 535.28 m between 28 Mar and 3 Apr 2023 (recorded on 7:00 am) while the outflow was stable at 851.00 m³/s between 28 Mar and 3 Apr 2023.

Mekong water levels this week remain as normal condition—with 10 out of 22 stations have water levels below their long-term average. In general, this hydrological condition is influenced by the inflows from the upper Mekong River in China and dam operations in the tributaries of the Lower Mekong River Basin.

Stay updated with our river monitoring and forecasting to better prepare for flood and drought events. Find more details at <https://www.mrcmekong.org/>.

The flow volume of the Tonle Sap Lake is lower than its LTA (about 88%). From next week, the flow is expected to be decreasing due to no rainfall is forecasted in the inflow catchments of the Tonle Sap Lake.

From Kratie to Kompong Cham, the water levels will most likely go down. The water levels – at Neak Luong on the Mekong River, from Prek Kdam to Phnom Penh Port on the Tonle Sap, and from Chaktomuk to Koh Khel on the Bassac – are forecasted to stay below their LTA.

The situation in Tan Chau on the Mekong River and Chau Doc on the Bassac River is expected to remain fluctuating. In Tan Chau and Chau Doc, the fluctuation of water levels was higher than their LTA level during the monitoring period, which were **considered critical**.

Since the third week of September 2022, water levels across most monitoring stations in the LMB have increased due to the above-average rainfall but still staying lower than their LTA value (from middle to lower stretches within the LMB). The preliminary analysis of the hydrological conditions in the LMB over July–December 2020 and November 2020 to May 2021 was done as [Situation Report](#), which can be used as reference for the trend of water level and flows of the Mekong River Basin.

The contribution to the Mekong River's flow from the UMB in China (Yunnan component) is about 16% by the time the river discharges through the Mekong Delta into the Sea. By far the major contribution comes from the two major 'left-bank' (Eastern) tributaries between Vientiane – Nakhon Phanom and Pakse – Stung Treng, which together contribute more than 40% of the flows.

7.3 Flash flood and its trends

With the predicted of rainfall for the coming week as mentioned earlier in [section 6.1](#), major flash floods are not likely to happen in the LMB.

7.4 Drought condition and its forecast

During Mar 27-Apr 2, the LMB was much better than the previous week of Mar 20-26. However, moderately dry condition remained in most areas of the middle and lower parts covering from Chaiyaphum of Thailand to Savannakhet of Lao PDR in the east and down to Kampot of Cambodia and Dak Lak of Viet Nam. Those specific drought hotspots are considered normal as they are caused by dry soil moisture phenomenon during dry season.

For the coming three months, **March** is generally wet in the north and south while middle part is likely to be normal. **April** is forecasted to receive average rainfall all over the region. But **May** is likely to be severely dry over the 3S area and moderately dry in the south-east covering eastern part of Cambodia and Viet Nam.
